

Web Development Performance Analysis Report

Website: Ecole Globale – Girls Boarding School

URL: <https://www.ecoleglobale.com/>

Prepared for: Eduminatti – Web Development Internship Assessment

Date: 6 February 2026

1. Objective of the Assessment

The objective of this assessment is to analyze the **page load performance, accessibility, and technical structure** of the Ecole Globale website and to suggest **clear, practical development improvements**.

This review focuses on:

- How the website performs for real users
- Why mobile users face performance issues
- What developers can realistically improve in code, design, and functionality

Special emphasis is placed on mobile performance, as most parents and students access educational websites on mobile devices.

2. Tools Used for Analysis

The following industry-standard tools were used to analyze the website's performance, accessibility, and user experience:

- **Google PageSpeed Insights**
Used to evaluate mobile and desktop performance, Core Web Vitals, accessibility, best practices, and SEO metrics.
- **Google Lighthouse**
Used to analyze performance diagnostics, Core Web Vitals, accessibility issues, and overall web best practices.
- **GTmetrix**
Used to assess page load performance, structure score, Web Vitals (LCP, TBT, CLS), and optimization opportunities.
- **Chrome DevTools (Performance & Network Panels)**
Used to identify render-blocking resources, unused JavaScript and CSS, large network payloads, and causes of layout shifts.

3. Overall Performance Summary

PageSpeed Insights Overview

Category	Mobile	Desktop
Performance	47(Poor)	90(Good)
Accessibility	69	78
Best Practices	96	96

SEO	85	85
Core Web Vitals	Failed ✖	Passed ✔

Key Insight:

The website is technically strong on desktop but not optimized for mobile, which negatively impacts user experience and search ranking.

4. Mobile Performance Analysis (Critical Area)

Mobile performance is the primary weakness of the website.

Core Web Vitals – Mobile

Metric	Value	Status	Meaning
FCP	2.3 s	Needs Improvement	Content appears late
LCP	5.8 s	Poor ✖	Main content loads very late
Speed Index	7.4 s	Poor ✖	Page feels slow
TBT	90 ms	Good ✔	Interactions respond well
CLS	0.525	Poor ✖	Layout shifts during load

Result:

Core Web Vitals fail on mobile, which can lead to higher bounce rates and reduced user trust.

5. Desktop Performance Summary

Desktop performance is stable and fast, proving that the server and architecture are capable.

Metric	Value
Performance Score	90
LCP	0.9 s
CLS	0.005

Observation:

The issue is not infrastructure, but missing mobile-first optimization.

6. Key Technical Issues

Issue	Technical Impact
Render-blocking CSS & JS	Delays first paint on mobile
Large image (~3.3 MB mobile)	High LCP and slow loading
Unused JS/CSS (~500 KB)	Extra download & execution

Missing image dimensions	Layout shifts (CLS)
Font loading delays	Late text rendering

7. Development-Level Improvements

These are practical improvements developers can apply directly:

- Convert all large images to **WebP / AVIF**
- Apply lazy loading for below-the-fold images
- Remove unused JavaScript and CSS
- Defer non-critical JavaScript execution
- Inline critical CSS for above-the-fold content
- Improve browser caching and use a CDN
- Optimize font loading using font-display: swap **Result:**

Faster mobile load, reduced CLS, and improved Core Web Vitals.

8. Page Design & Functionality Improvements

Page Design Improvements

- Simplify the homepage layout for mobile by reducing visual clutter.
- Maintain consistent spacing and alignment to prevent layout shifts.
- Improve font hierarchy so headings and content are easier to scan.
- Highlight key actions (Enquiry / Contact) with better button placement.
- Improve contrast between text and background for readability.

Functionality Improvements

- Improve mobile navigation menu responsiveness and touch accuracy.
- Ensure all buttons, links, and forms are easily clickable on small screens.
- Optimize form validation with clear error and success messages.
- Reduce unnecessary animations that affect mobile performance.
- Improve interaction speed by minimizing JavaScript execution on user actions.

Why this matters:

Parents browsing schools expect **clarity, speed, and ease of use**. These changes directly improve usability and trust.

9. Business & User Impact

Improving mobile performance and usability will:

- Reduce bounce rate from mobile users
- Increase time spent on the website
- Improve Google search rankings
- Build trust with parents and students
- Create a smoother and more inclusive experience for all users

10. 30-Day Optimization Roadmap

Week 1

Image compression, WebP/AVIF conversion, missing image dimensions, alt text fixes

Week 2

Remove unused JS/CSS, defer scripts, improve caching strategy

Week 3

Fix CLS issues, optimize font loading, improve mobile layout stability

Week 4

Accessibility fixes, final PageSpeed & GTmetrix audit, performance comparison report

11. Conclusion

The Ecole Globale website has a strong technical foundation, especially on desktop.

However, mobile performance, layout stability, and usability require immediate improvement.

By applying focused development, design, and functionality optimizations, the website can achieve:

- Better Core Web Vitals
- Faster mobile load times
- Improved SEO performance
- A smoother, more trustworthy user experience

This assessment demonstrates not only what needs improvement, but how a developer can practically implement these changes in a real production environment.
